

# City Comparison

Restaurant Comparison between New York, Toronto and Paris

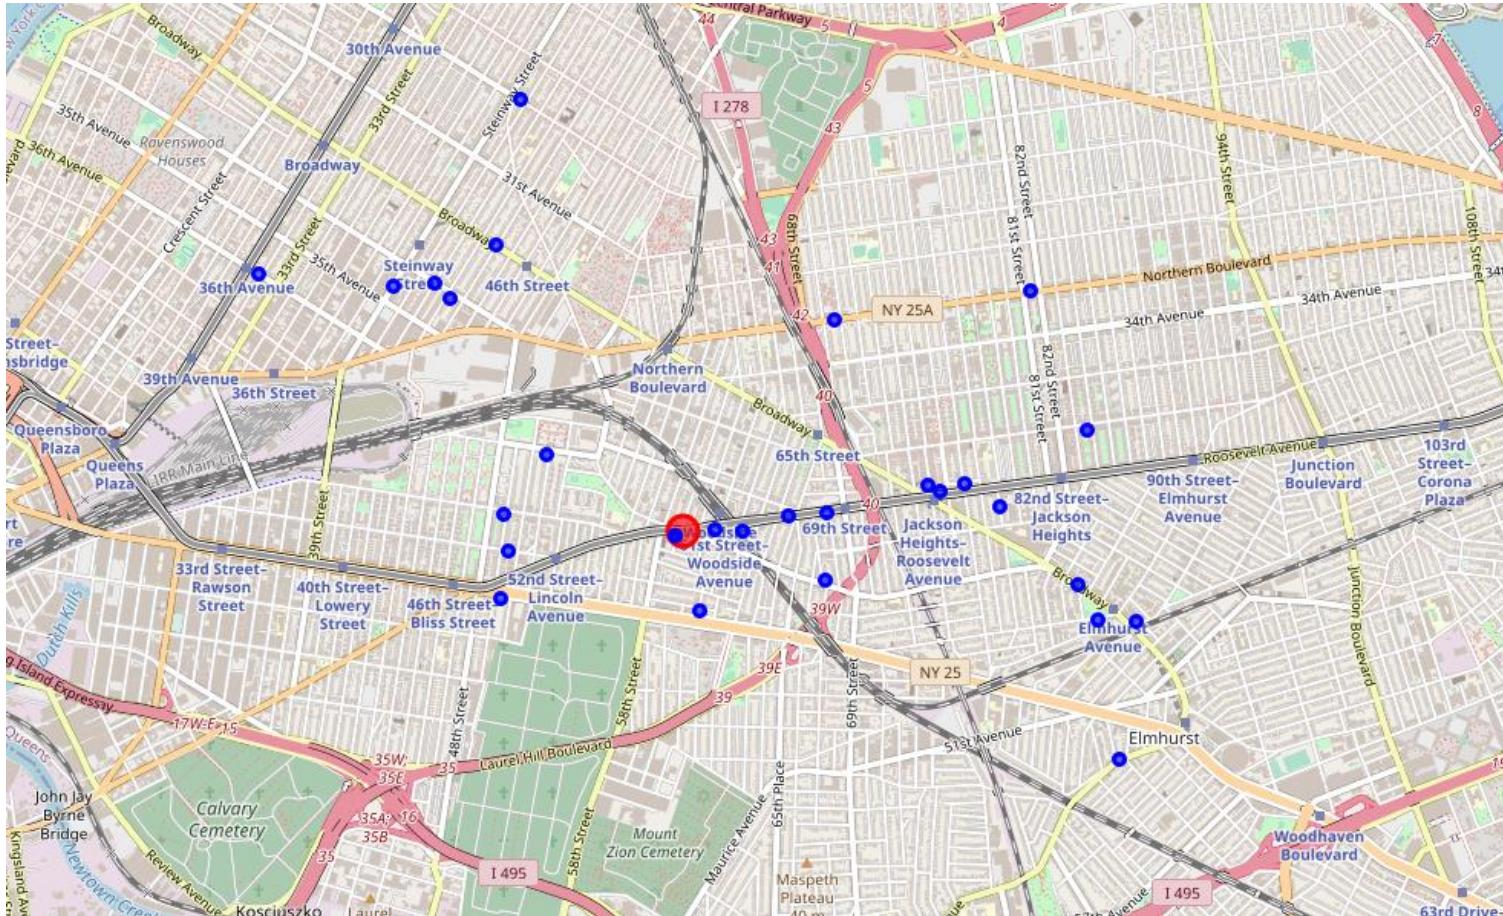

# City Comparison

- We will attempt to request restaurant data from foursquares and then plot them on a map to see which city has the most restaurants and how close they are from the center of the cities.
- When travelling to these cities it will be more beneficial to have more restaurants in the higher density when you are that city.
- If your main reason to travel is for the food, visiting a city with a higher density of restaurants will allow you to try a wider variety of food without having to travel far distances.

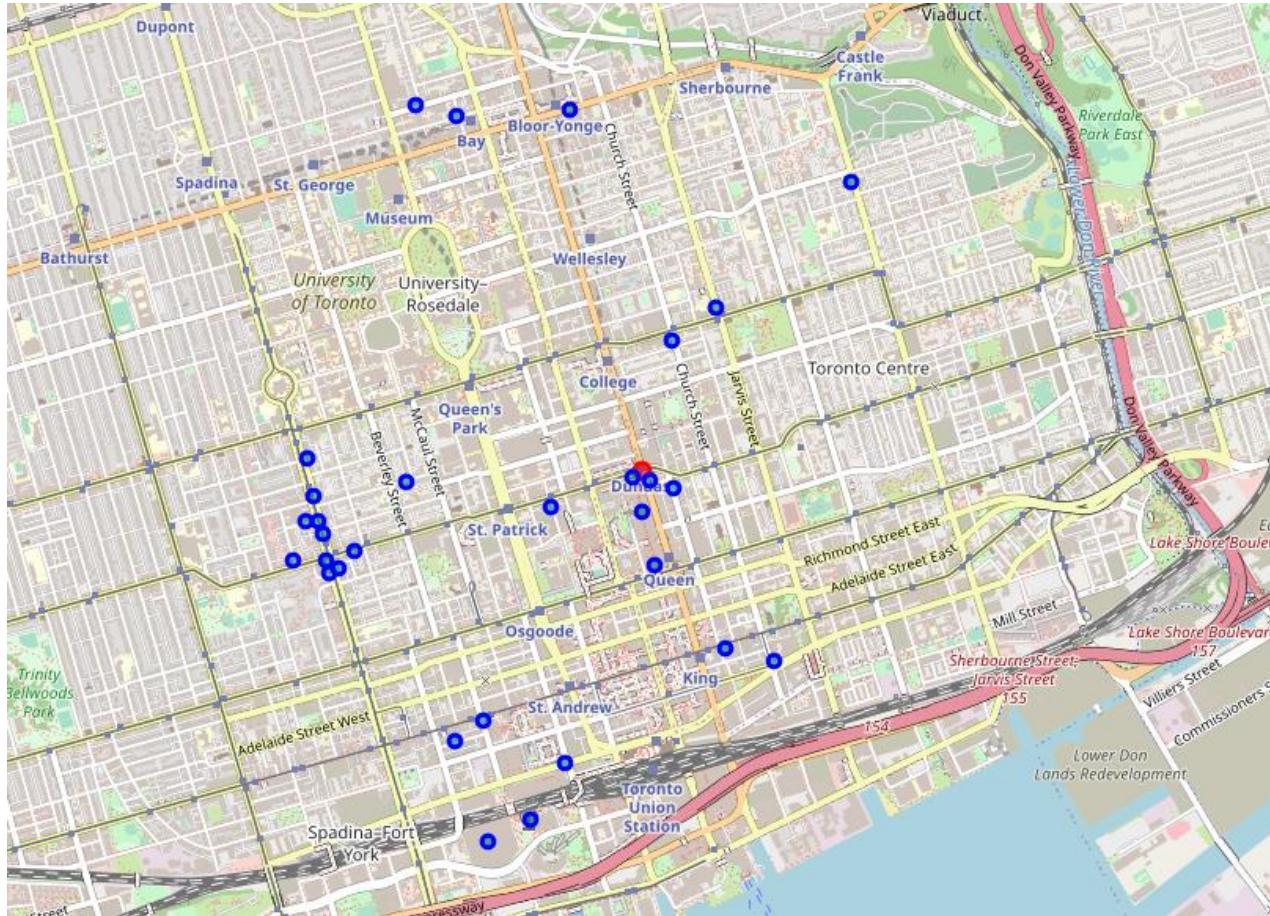

# Data acquisition and clean

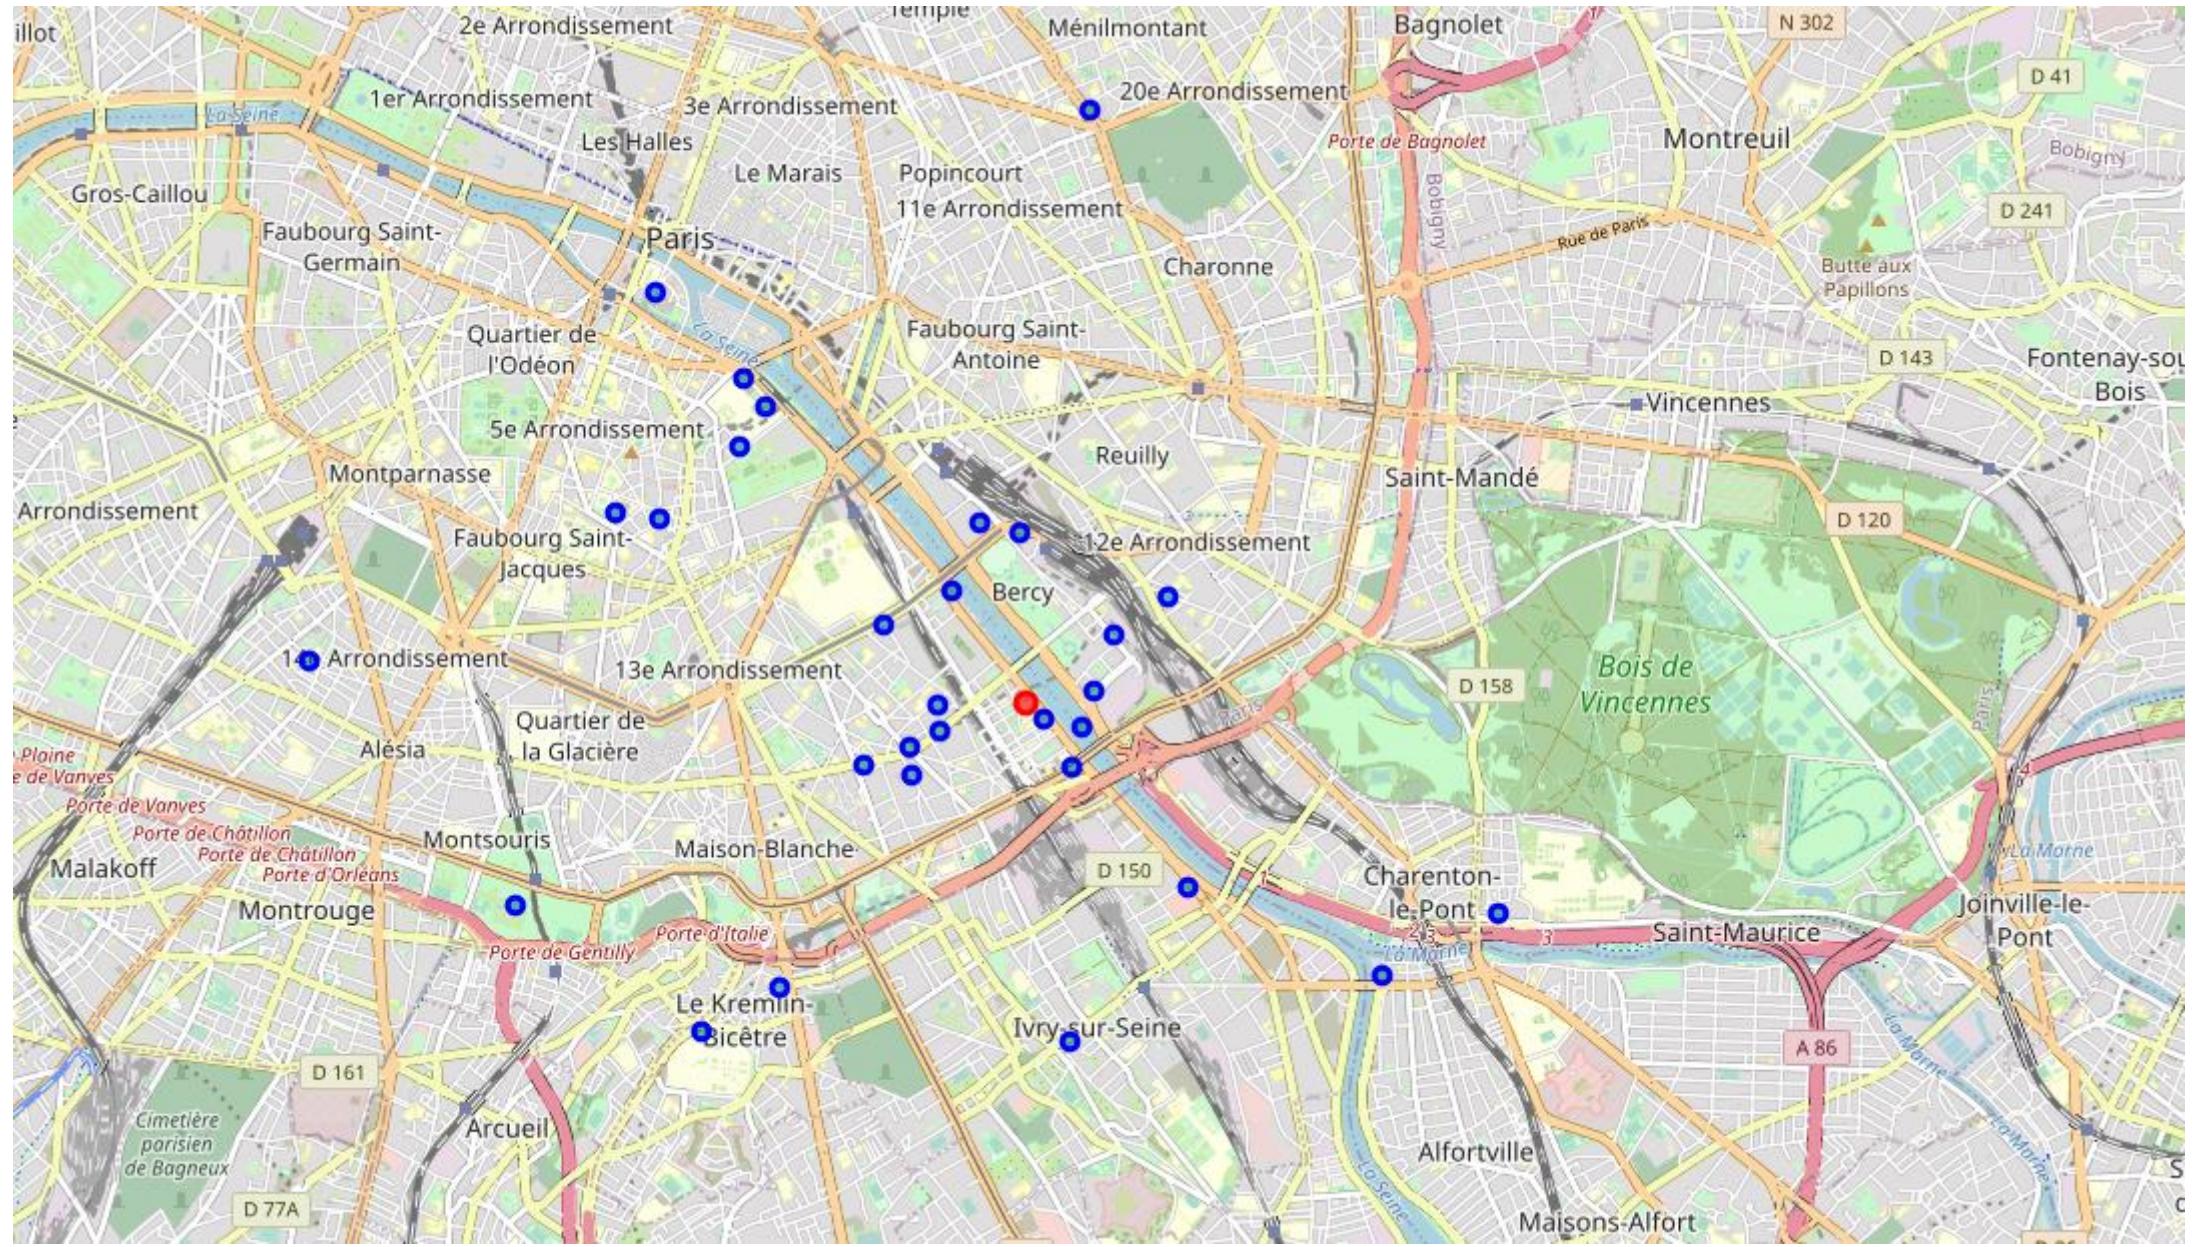

- First we will determine the center points of these cities and acquire address to determine the coordinates of the location
- Then we will access the foursquares API using the coordinates above with a radius of 50000m and the search query of restaurant.
- Then we will filter the data to by the categories and assign it to a data frame.
- Then we will plot all of the restaurants on a map within the determined radius and based on the 3 maps we will be able to see the quantity and density of restaurants in each city.

# Restaurants in New York

# Restaurants in Toronto

# Conclusion

- After examining the graphs we can see that Paris has the most restaurants, but the density is low compared to the other 2 cities.
- New York has the highest density of restaurants which will require the least amount of travel between restaurants
- And Toronto has one highly dense area with maybe other low-density areas which will require the most travel between restaurants
